What is light pollution?

Light pollution is the sum of adverse effects of obtrusive artificial light at night (ALAN). It comprises:

- Glare
- Light trespass (spill light)
- Skyglow – resulting in a brighter night sky which impedes our ability to see the stars.

Skyglow is caused by scattering of light by air molecules and aerosols in the Earth's atmosphere.

Airglow seen from space

Natural airglow photographed from the ISS by Italian astronaut Samantha Cristoforetti in 2014.

Airglow is emission by air molecules high up in the atmosphere.

Skyglow adds to the low brightness natural airglow.

Six reasons for good lighting

- ALAN may have an adverse impact on human health.
- ALAN can be damaging to the bio-environment and to biodiversity
- Poorly installed outdoor lighting, especially installations that allow light to be projected upwards, wastes electricity.
- **ALAN brightens the night sky and this makes it more difficult to see the stars.**
- Good outdoor lighting installations promote greater public safety.
- Dark skies can be a resource for a sustainable economy through astro-tourism.

Measuring the brightness of the night sky

The Bortle scale (J Bortle 2001) uses a nine-point scale.

- Bortle class 1 is for the darkest sites.
- Bortle class 9 is for the most light polluted sites.
- The Bortle classes are a scale based on the faintest stars just visible to the naked eye.
- ALAN reduces visibility of stars when they are viewed against a bright background sky.

The Bortle scale and Spoelstra nomogram

Quantitative measures of sky brightness

A popular unit of sky brightness is magnitudes per square arc second. Stellar magnitude is an inverse logarithmic scale used by astronomers (larger numbers refer to fainter stars, 2.5 magnitudes = factor of 10.).

About 21.8 mag/sq arc sec corresponds to a natural unpolluted dark sky (Bortle class 1).

Many highly polluted urban sites have sky brightness ~16 to 18 mag/sq arc sec, Bortle class 8 or 9 and only a dozen (or fewer) stars visible.

Photometric units for sky brightness

A useful unit for sky brightness is the S_{10} unit – the equivalent number of 10^{th} magnitude stars per square arc minute that correspond to the sky brightness level.

Unpolluted sky is at about $145 S_{10}$ (or 21.8 mag/sq sec arc).

A heavily polluted sky at 16.7 mag/sq arc sec has about $27,000 S_{10}$.

Note that magnitudes refer to the visual (yellow) passband to which our eyes in daytime are most sensitive ($\lambda_{\text{max}} = 555 \text{ nm}$).

Photometric SI units

The surface brightness or luminance of the night sky is also measured in SI (Système International) photometric units of milli-candela per m^2 .

The natural airglow is about $0.25 \text{ mcd}/\text{m}^2$ (unpolluted night sky) though the figure is somewhat variable in direction, time and location.

Significantly polluted skies have luminance $> 1 \text{ mcd}/\text{m}^2$.

The candela is defined in terms of the visual photopic passband, as defined by CIE and peaking at 555 nm. This bandpass is not very sensitive to blue light ($\lambda < 500 \text{ nm}$).

What is a dark sky oasis?

A **dark sky oasis** (also often referred to as a '**dark sky place**') is a location where the night sky is protected by an outdoor lighting policy, or in legal terms, by *a lighting ordinance*.

This limits the amount and the wavelengths of light that shine upwards into the sky. Blue light ($\lambda < 500$ nm) is especially harmful, as it scatters the most.

Most dark sky oases will have controls on

- street lighting,
- the lighting of sports facilities at night,
- outdoor lighting of commercial facilities (ports, factory yards),
- flood lighting of buildings.

Accreditation agencies for dark sky oases/places

International agencies:

- The International Dark-Sky Association (IDA), Tucson, Arizona
- The Starlight Foundation (Tenerife, Canary Is, Spain).

National agencies include:

- The Royal Astronomical Society of Canada (RASC)

By mid-2020, there were 223 dark sky places in 27 countries with accreditation, covering over 20 million hectares.

The IUCN classification scheme for dark sky places

Class	Type of Dark Sky Place	Number world-wide (May 2020)
1	Dark sky astronomy site	15
2	Dark sky park (protected natural area)	114
3	Dark sky heritage site	9
4	Dark sky outreach site (e.g. public observatory)	25
5	Dark sky reserve (mix of cooperating community, rural and natural area jurisdictions)	21
6	Dark sky community (rural area, village or town)	39
	TOTAL	223

IUCN = International Union for the Conservation of Nature. The classification is from the IUCN Dark Skies Advisory Group

The New World Atlas of Artificial Night Sky Brightness

Falchi, F.; Cinzano, P.; Duriscoe, D.; et al. (2016). The new world atlas of artificial night sky brightness. *Science Advances*, 2, 1-25.

The atlas is based on satellite data of light going from Earth into space recorded in the years 2013-2014, in wavelength interval 500-900 nm.

Computer modelling then predicts the night sky brightness in $\mu\text{cd}/\text{m}^2$ that would be observed from the ground.

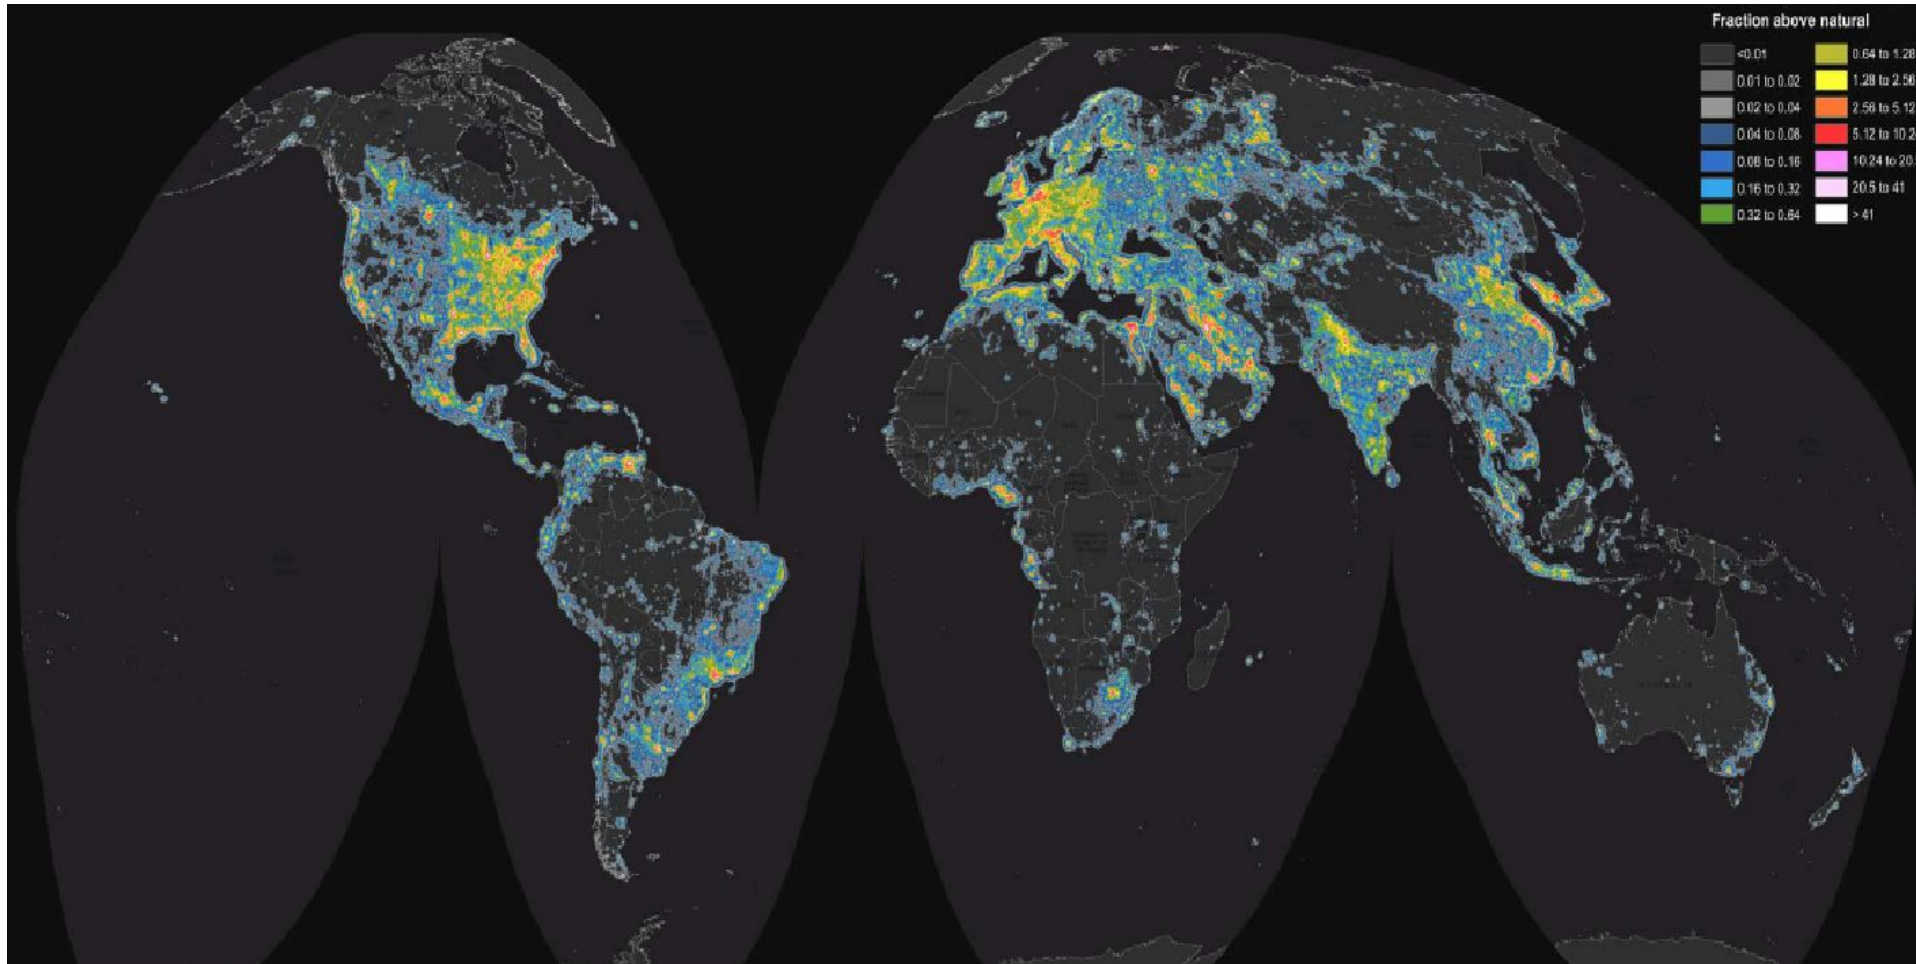

The New World Atlas of Artificial Night Sky Brightness

Predictions of the New World Atlas:

- 80 per cent of the world and more than 99 per cent of the US and European populations live under light-polluted skies.
- The Milky Way is hidden from more than one third of humanity, including 60 per cent of Europeans and nearly 80 per cent of North Americans.
- 23 per cent of Earth's land surface area between 75°N and 60°S, experience light-polluted nights.
- 88 per cent of Europe and nearly half the area of the US experience light-polluted nights.

The New World Atlas of Artificial Night Sky Brightness

The red areas are highly light-polluted and have typically 5 to 10 times the natural night sky brightness, generally in excess of $1250 \mu\text{cd}/\text{m}^2$ and up to $2500 \mu\text{cd}/\text{m}^2$.

Impacts of ALAN on the visibility of stars

Visual Magnitude	Magnitude Range	Number of Stars per Range (in a full sphere)	Cumulative Number of Stars	Approx. number of stars visible above 10°
-1	-1.50 to -0.51	2	2	1
0	-0.50 to +0.49	6	8	3
1	+0.50 to +1.49	14	22	9
2	+1.50 to +2.49	71	93	38
3	+2.50 to +3.49	190	283	116
4	+3.50 to +4.49	610	893	368
5	+4.50 to +5.49	1,929	2,822	1165
6	+5.50 to +6.49	5,946	8,768	3621
7	+6.50 to +7.49	17,765	26,533	10958
8	+7.50 to +8.49	51,094	77,627	32059

Classifications of Dark Sky Oases (DSOs)

We sort the DSOs by two characteristics: night sky quality and land use type.

IDA International Dark Sky Places Programme

153 designations on six continents; 104,000 km² protected.

The IDSP Programme

- Demonstrates DSO conservation at scale in a variety of geographies and societies
- Recognises DSOs not just for being dark, but for efforts made toward achieving conservation goals
- Requires a comprehensive, peer-reviewed nomination
- Establishes a global network of DSOs that share talent, resources, and information

The Starlight Declaration (La Palma, 2007)

www.fundacionstarlight.org

The Starlight Foundation: the commitment with Starlight Declaration

“Starlight” as a whole, is considered by UNESCO to be an associated action that has the support of the International Astronomical Union (IAU) and the World Tourism Organization (UNWTO).

MAIN GOALS :

- ❖ Protection of night skies
- ❖ Smart lighting and energy saving
- ❖ Cultural dissemination of astronomy
- ❖ Star Tourism

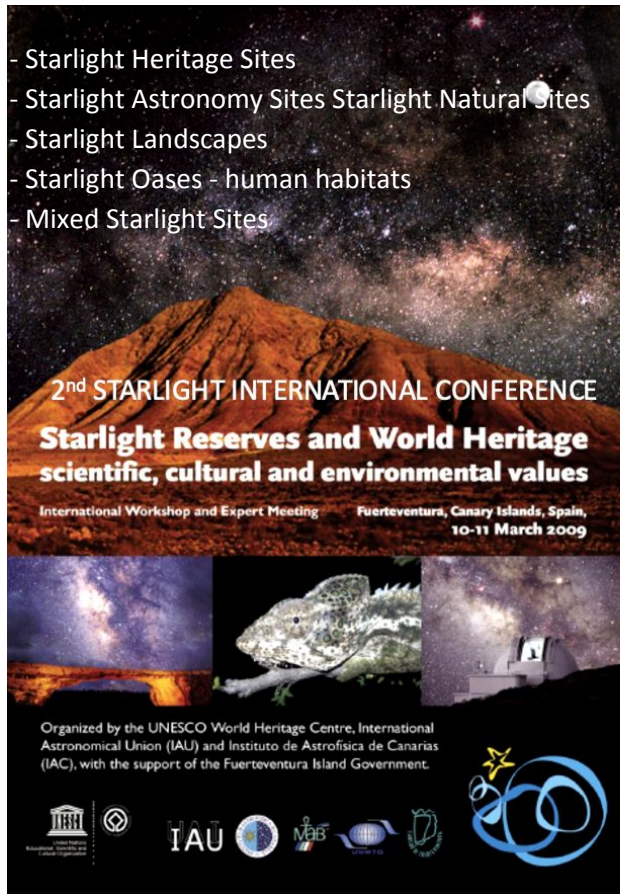

The International Starlight Certification: bringing for first time science and tourism together

- Starlight Heritage Sites
- Starlight Astronomy Sites
- Starlight Natural Sites
- Starlight Landscapes
- Starlight Oases - human habitats
- Mixed Starlight Sites

2nd STARLIGHT INTERNATIONAL CONFERENCE
Starlight Reserves and World Heritage scientific, cultural and environmental values
International Workshop and Expert Meeting Fuerteventura, Canary Islands, Spain, 10-11 March 2009

Organized by the UNESCO World Heritage Centre, International Astronomical Union (IAU) and Instituto de Astrofísica de Canarias (IAC), with the support of the Fuerteventura Island Government.

STARLIGHT RESERVE CONCEPT

UNWTO Knowledge Network

The Starlight Certification seeks to guarantee the capacity to enjoy the view of the stars and to discover the associated scientific, cultural, natural and scenic values.

The Socio-Economic Impact of Astro-tourism

Annual growth up to 350%

Montsec...32.000 visitors, 2.5 millions €/2018

Iles Atlanticas...71.000 visitors for Starlight activities

Tenerife200.000 visitors

Mackenzie & Aoraki/Mt Cook 150.000 visitors

La Palma ...more than 70 business or registered projects, 29.5 millions €/year (Cabildo de La Palma)

From Airbnb study in Starlight sites:

Antofagasta (Chile)..... 327%

La Palma (Spain) 90%

Yarmouth (Canada)..... 221%

SF Winner in FiturNext 2020 Challenge among more than 250 innovative sustainable tourism projects of more than 50 countries.

Antonia Varela

The evolution of light sources and luminaires

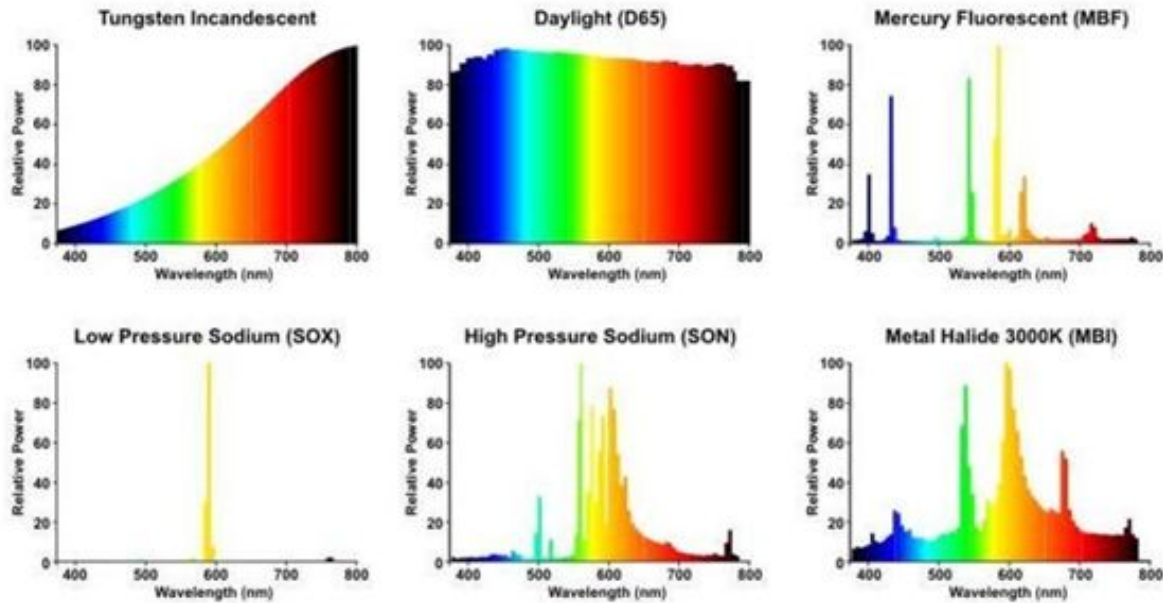

- From Torch to LED: A long way towards the energy efficiency

3 major groups (Filament, Fluorescent and High Intensity Discharge)

The evolution of light sources and luminaires

- Spectral content of light sources and blue content

The evolution of light sources and luminaires

- Initially, luminaires functioned as housings for the light sources without any control on light distribution.
- Later street luminaires distributed the light mainly towards the road but also upwards.
- Street luminaires with conventional sources had/have cut-off design and had better optics while additional accessories reduce spill light.
- LED street luminaires are based on lens and reflector design and can achieve maximum control of light distribution.

The evolution of light sources and luminaires

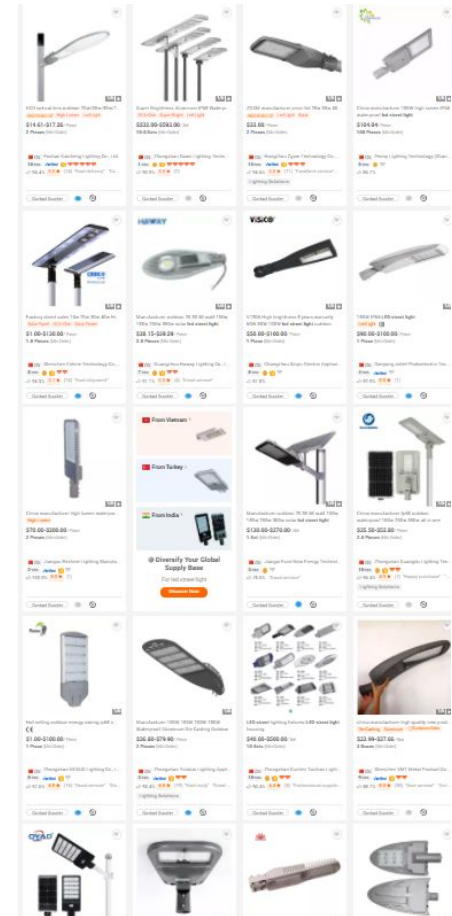

How LEDs revolutionized the luminaire technology and lighting control

- Increased efficiency compared to traditional sources (expect from LPS 😊)
- Small light source compared to traditional lamps
- Lens, diffuser and reflector design is more flexible than ever
- LED permits full control on luminous flux over time or via adaptive systems
- Luminaire can be equipped with LEDs with various colour temperatures
- Tunable white (e.g. 2200-3000K) tends to become a standard for both indoor and outdoor applications
- Huge energy saving potentials compared to existing lighting installations

The evolution of light sources and luminaires

But why did LED technology create a negative reputation?

- Massive renovations with priority in energy saving
- Endless number of cheap and low quality “me-too” products
- Bad or no lighting design at all
- Noticeable difference of efficacy between warm and cool white LED (during the early days) which promoted >5000K
- No commissioning, measurements and monitoring
- Lot of complains about blueish light and glare

The evolution of light sources and luminaires

Some thoughts...

- Each light source is not an “*a priori*” source of light pollution
- Obtrusive light & sky glow are affected by the combination of light sources, luminaires, lighting design, over-illumination, etc.
- Traditional light sources offered only certain wattages, while luminaire technology was limited by the size of the light source and the optics
- Today’s technology offers almost full control of light distribution and fine-tuning of emitted spectrum.
- The synergy between new luminaire technology, modern light sources and lighting control can significantly reduce the adverse effects of ALAN

Recommendations to COPUOS

Aspirational night sky brightness limits recommended for dark sky oases

IUCN class	DSO type in terms of natural airglow	Maximum sky brightness recommended			
			$\mu\text{cd}/\text{m}^2$	mag/sq arc sec	
1	Astron. observatory	1.10x	<260	>21.7	
2	Dark sky park	1.50x	<360	>21.4	
3	Dark sky heritage site	2.75x	<660	>20.7	
4	Dark sky outreach site	2.0x	<480	>21.0	
5	Dark sky reserves	2.0x	<480	>21.0	
6	Dark sky community	3.0x to 4.0x	<750 to <1000	>20.6 to >20.3	
		rural semi-urban	rural semi-urban	rural	semi-urban

Recommendations to COPUOS

- In all protected dark sky oases the default condition should be no artificial light.
- In ecological reserves and similarly sensitive sites with little or no human presence at night, artificial light should not be used. If it is used, it should be a narrowband amber LED or equivalent emitting no light at $\lambda < 500$ nm. Lighting should be strictly controlled and switched on only when it is needed.
- If phosphor-converted amber LED lights are used, the amount of blue light ($\lambda < 500$ nm) should be below 5 % of the total spectral power. Generally this requires using LEDs with a correlated colour temperature of 2200 K or less.
- All exterior lights should only distribute light below the horizontal, and the upward light output ratio (ULOR) should be no more than 0.5 %. This requires luminaires to be mounted horizontally and have flat screen glass below the light source.

Recommendations to COPUOS

- No development in or near highly ecologically sensitive sites should be permitted.
- Monitoring of night-time conditions in/near dark sky oases is encouraged through a combination of ground-based and remote sensing methods.
- Active management of natural night-time darkness as a natural resource is encouraged through recognised conservation best practices.
- Restoration plans should be implemented when sky brightness thresholds are routinely exceeded.
