Fundamental Role of Reference Frame

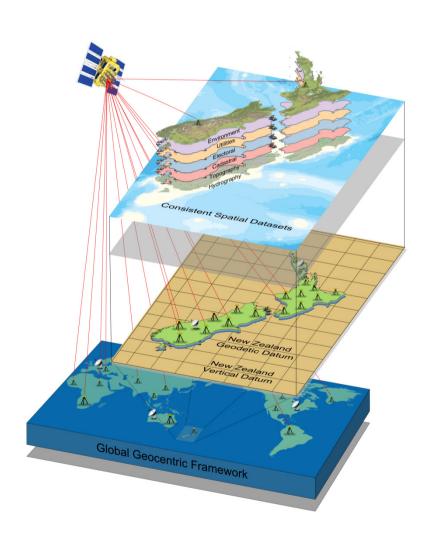

Fundamental Role of Reference Frame

Fundamental Role of Reference Frame

Requirements of a National Reference System

- A coordinate framework that is accurate, stable, reliable and accessible
- Direct linkage to International Reference Frames
- Simple for users to connect to and use
- Physical infrastructure may include GNSS CORS and traditional geodetic survey marks
- Systems and tools to allow connection to the coordinate reference system and transformation of legacy data to the current reference system

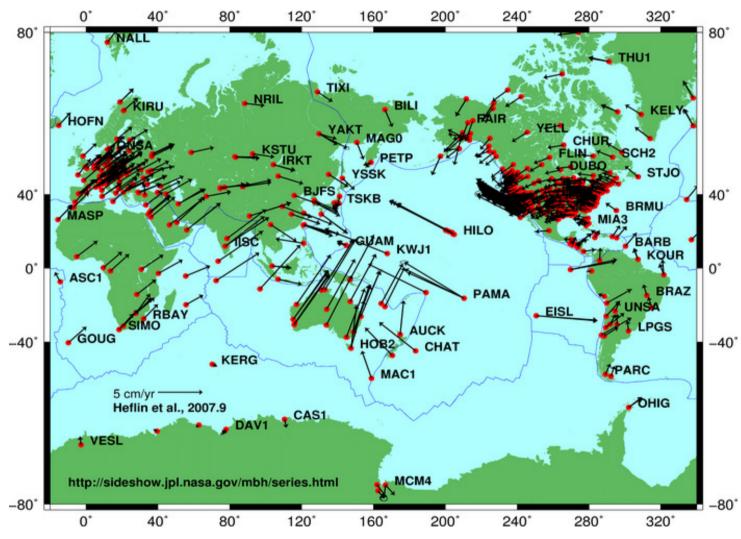

Crustal Dynamics

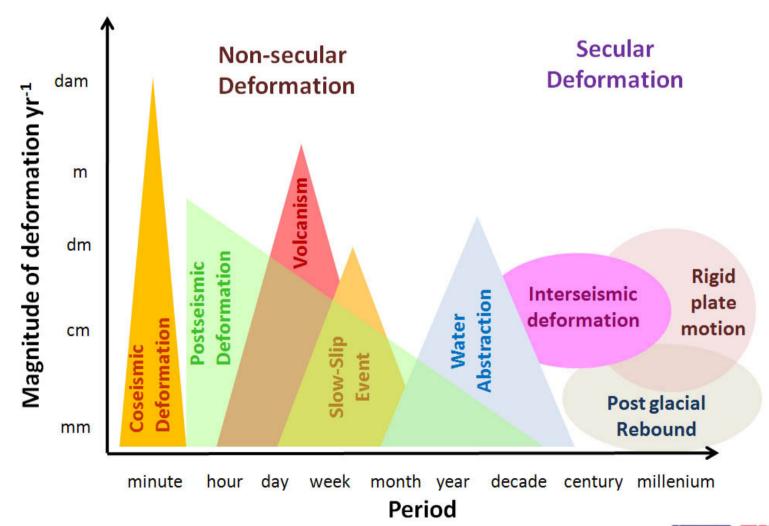

Temporal and spatial extent of deformation

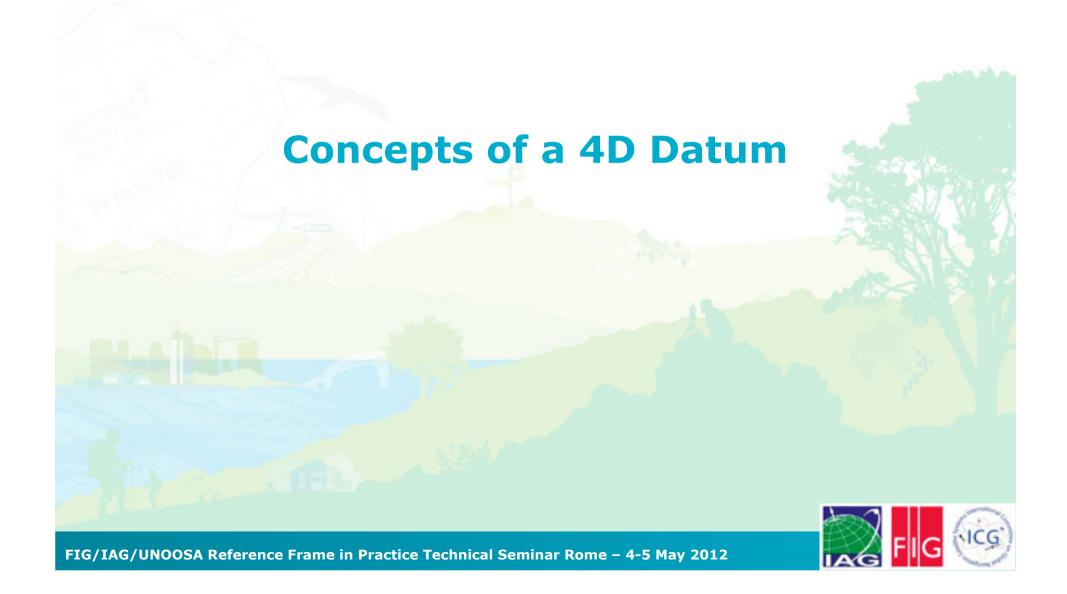

Datum Types

Static Datum (2D and 3D)

Coordinates are fixed at a reference epoch

Does not incorporate the effects of plate tectonics and deformation events Coordinates slowly go out of date, need to change periodically which is disruptive

Dynamic datum (4D)

Incorporates a deformation model to manage changes (plate tectonics and deformation events)

Coordinates change continuously

Can be confusing and difficult to manage

Semi - dynamic datum

Incorporates a deformation model to manage changes (plate tectonics and deformation events)

Coordinates fixed at a reference epoch

Change to coordinates is minimised

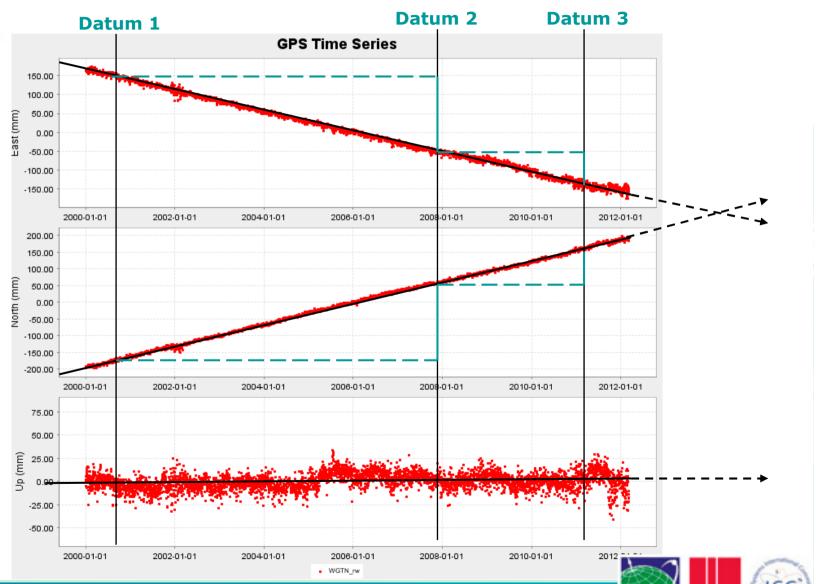

Constant motion through time

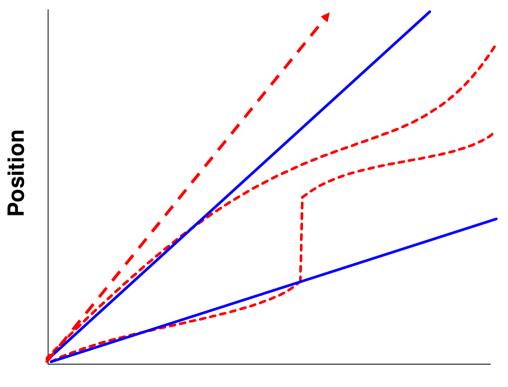

The dynamic world

The ideal world!

Need to accommodate error in model or changes in deformation Need to accommodate local and spatially complex deformation

Time

Options - Error in model or changing deformation

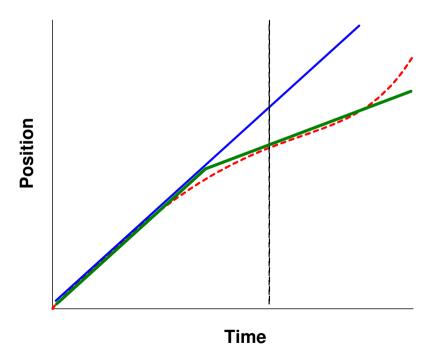

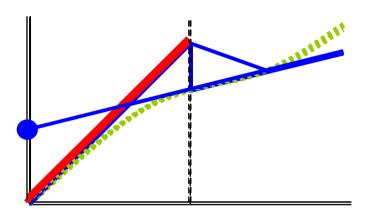

Steer to a new model

Jump to the new model

Revise the previous model

Ignore the previous model

Solution Revise the previous model always preserves the best estimate of past and future position and velocity

Options - Spatially complex deformation

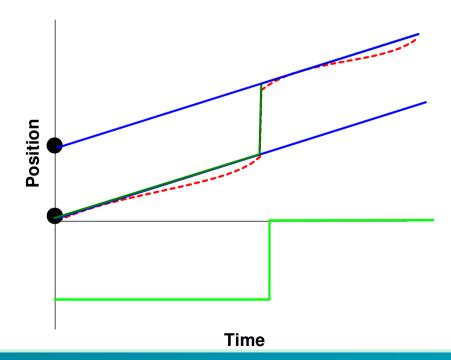

The deformation event is not incorporated into the deformation model (dot is the base epoch coordinate of the mark)

The 'patch' deformation model – in this case a discrete event

The trajectory of the mark – incorporated the national deformation model and the 'patch'

The base epoch coordinate is changed to incorporate the offset calculated from the patch

Coordinates for times after the event just use the national deformation model and coordinates before the event include the patch.

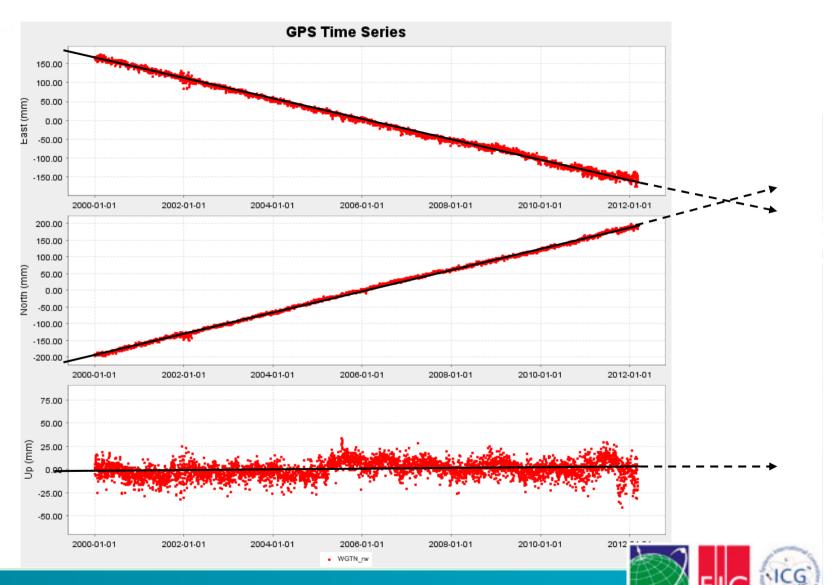

Constant motion through time

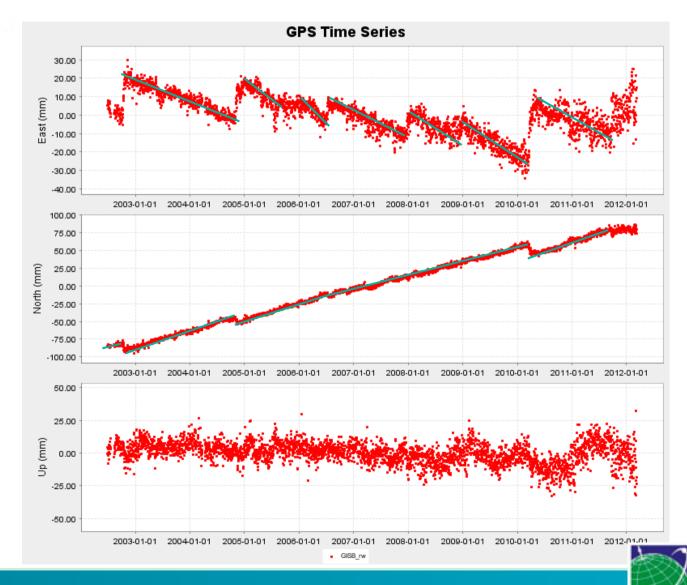

Episodic events

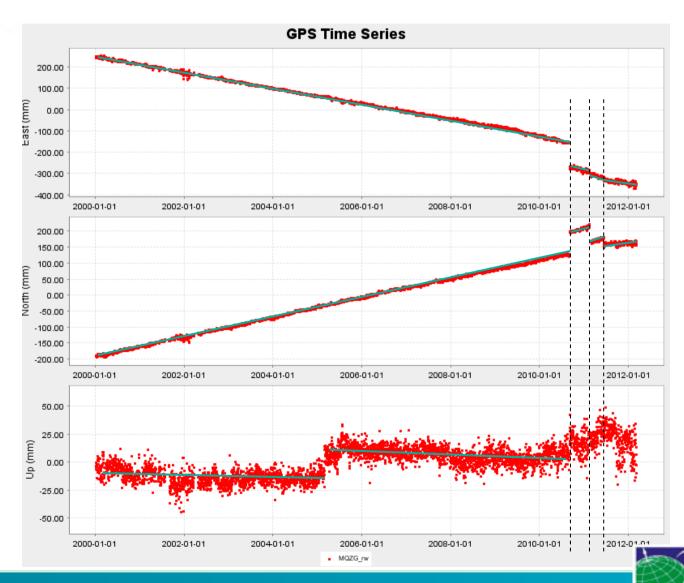

Multiple events

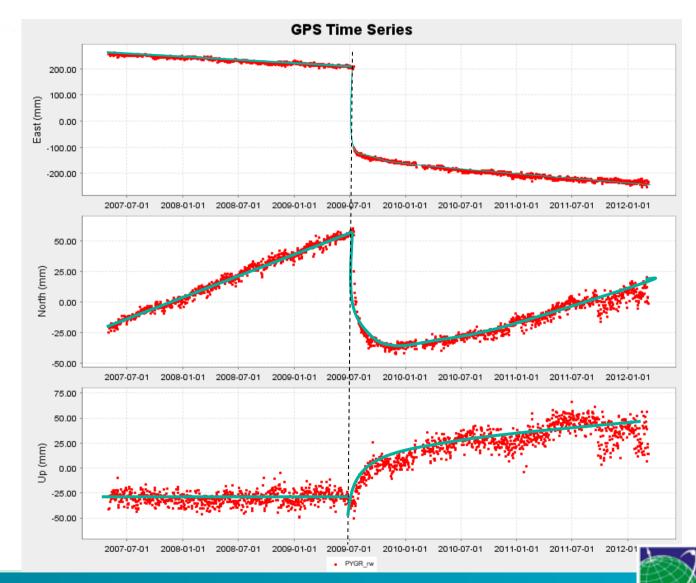

Earthquake and postseismic deformation

Modelling the deformation

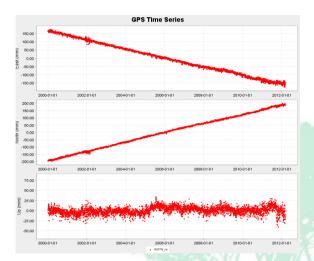

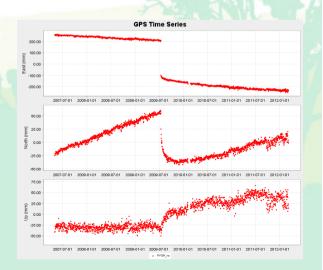

Options – regional deformation

- Simple rectangular grid (simplest method)
- Complex grid (eg curvilinear grid)

Options – complex deformation

- Densify the national deformation model (model becomes very complex)
- need a detailed triangulated grid becomes complex
- define a local 'patch' for the model (covers the area of the event with zero deformation at the boundaries)
- change coordinates

The pros and cons of static, semidynamic datum and dynamic datums

Advantages of a Dynamic or Semidynamic Datum

Maintains alignment with underlying global reference frames - ITRF

Lengthen the life of the datum

New observations can be integrated with old observations

Spatial accuracy of the geodetic network/datum is maintained or increased

Enables non-expert users to be isolated from the complexities of the dynamics (semi-dynamic datum only)

For practical purposes appears as a static datum (semi dynamic datum only)

Disadvantages of a Dynamic or Semi-dynamic Datum

Limited by the accuracy of the deformation model

Model can become complex over time to incorporate the effects of deformation events (e.g. earthquakes)

Coordinates need to be time tagged – cause confusion (dynamic datum only)

Most users do not know how to use a deformation model which is required to work with a dynamic datum

If using real time systems (CORS networks) need to use the deformation model to manage real time coordinates (semi-dynamic datums only)

Issues to consider

Accommodate vertical deformation

- vertical deformation trends may be obscured by much larger localised episodic or cyclic events
- triangulated or other irregular grid probably required

Latency

- may be considerable time between a deformation event and the 'patch' being implemented
- for discrete events deformation may continue for some time requiring different versions of the patch

Extension Offshore

- how do you model deformation offshore?
- offshore may need to incorporate global model express velocities as global rotations

Changing Reference Epoch

 may ultimately need to change the reference epoch once coordinates become inconveniently different from true current positions (semi-dynamic datum only)

Joining adjacent jurisdictions/datum's

Development of a Deformation Model

FIG/IAG/UNOOSA Reference Frame in Practice Technical Seminar Rome – 4-5 May 2012

Development of a Deformation Model

FIG/IAG/UNOOSA Reference Frame in Practice Technical Seminar Rome – 4-5 May 2012

Aim of a **Deformation Model**

Dynamic (kinematic) - ITRF

Application:

GNSS data processing & analysis (e.g. PPP, RTK, NRTK, DGPS, Static post-processing) Large-scale deformation analysis GGOS

Semi-dynamic (kinematic) datum Fixed epoch of ITRF

Application:

All other spatial applications
(e.g. cadastral, engineering,
mapping, precision agriculture,
mining, LiDar products)
terrestrial surveying
(e.g. TLS, total-station)

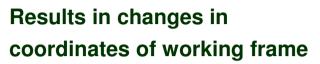

Classification of Deformation

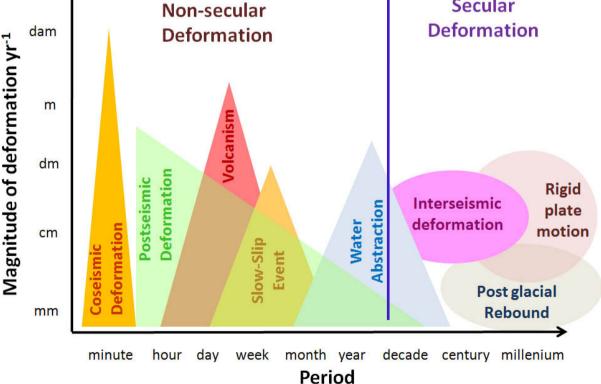

- patch model

- secular model

Secular

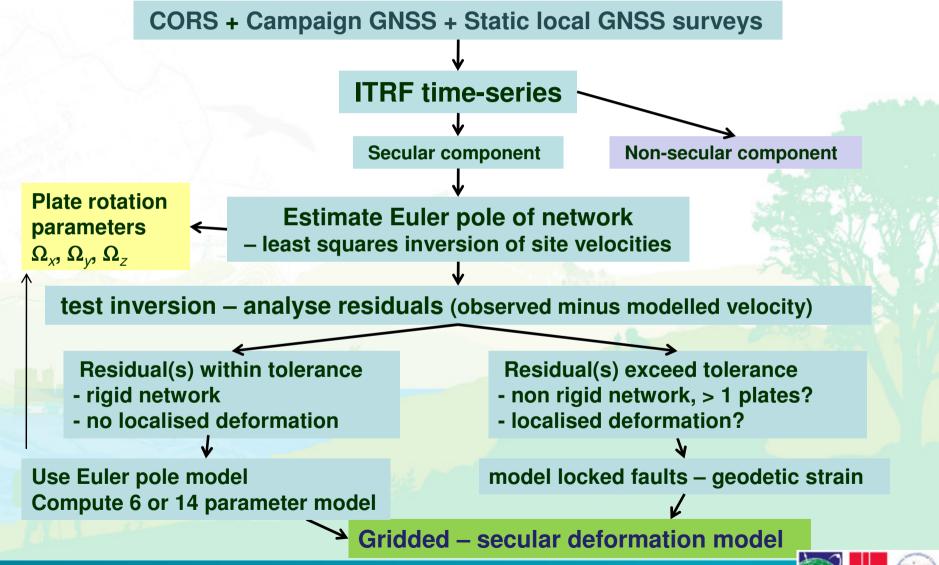

Developing a Secular Deformation Model

Secular Model format

aligned with current ITRF

no scale change / rate no translation / rate rotation of axes + rate

6 parameter transformation of Rx, Ry, Rz, + rates 3 parameter Euler propagation Ωx, Ω y, Ω z aligned with earlier ITRF realisation or non ITRS ellipsoid

scale change / rate translation / rate rotation of axes + rate

14 parameter transformation S, Tx, Ty, Tz, Rx, Ry, Rz, + rates

Gridded secular deformation model ITRF site velocities on a 1° or 0.1° grid

Site velocity estimated by bilinear interpolation (as used in geoid or grid distortion modelling)

Kinematic ITRF to Semi-kinematic ITRF by Transformation

14 parameter transformation

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{t_0} = \begin{bmatrix} T_x + \dot{T}_x(t - t_0) \\ T_y + \dot{T}_y(t - t_0) \\ T_z + \dot{T}_z(t - t_0) \end{bmatrix} + \left\{ S + \dot{S}(t - t_0) \right\} \begin{bmatrix} 1 \\ -\left\{ R_z + \dot{R}_z(t - t_0) \right\} \\ -\left\{ R_z + \dot{R}_z(t - t_0) \right\} \\ \left\{ R_y + \dot{R}_y(t - t_0) \right\} \\ -\left\{ R_x + \dot{R}_x(t - t_0) \right\} \\ \left\{ R_y + \dot{R}_y(t - t_0) \right\} \\ -\left\{ R_x + \dot{R}_x(t - t_0) \right\} \\ 1 \end{bmatrix} \cdot \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{t}$$

6 parameter transformation (no translation or scale)

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{t_0} = \begin{bmatrix} 1 & \left\{ R_z + \dot{R}_z(t - t_0) \right\} & -\left\{ R_y + \dot{R}_y(t - t_0) \right\} \\ -\left\{ R_z + \dot{R}_z(t - t_0) \right\} & 1 & \left\{ R_x + \dot{R}_x(t - t_0) \right\} \\ \left\{ R_y + \dot{R}_y(t - t_0) \right\} & -\left\{ R_x + \dot{R}_x(t - t_0) \right\} & 1 \end{bmatrix} \cdot \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_t$$

 t_0 is the reference epoch (years)

t is the epoch of measurement (years)

 $\dot{T}_x \dot{T}_y \dot{T}_z$ rate of change (m/yr) T_x , T_y , T_z Translation parameters (m)

 R_x , R_y , R_z Rotation parameters (radians) $\dot{R}_x \dot{R}_y \dot{R}_z$ \dot{S} Scale (unitless) rate of change (radians/yr)

rate of change (per yr)

Kinematic ITRF to Semi-kinematic ITRF by Propagation

Site velocity from Euler pole definition

$$\begin{bmatrix} \dot{X} \\ \dot{Y} \\ \dot{Z} \end{bmatrix} = \begin{bmatrix} \Omega_{Y}Z - \Omega_{Z}Y \\ \Omega_{Z}X - \Omega_{X}Z \\ \Omega_{X}Y - \Omega_{Y}X \end{bmatrix} \cdot 1E-6 \longrightarrow \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{t_{0}} = \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{t} + \begin{bmatrix} \dot{X} \\ \dot{Y} \\ \dot{Z} \end{bmatrix} \cdot (t_{0} - t)$$

 t_0 reference epoch of the semi-kinematic datum (in decimal years)

t epoch of measurement (in decimal years)

 $(\Omega_X, \Omega_Y, \Omega_Z)$ Euler pole (Cartesian rotation format)

 $(X, Y, Z)t_0$ semi-kinematic coordinates computed at the reference epoch (m)

(X, Y, Z)t kinematic ITRF coordinates at the measurement epoch (m)

(X,Y,Z) ITRF site velocity estimated from the Euler pole definition or interpolated from the secular deformation model (m/yr)

Gridded Deformation Models

Regular grid deformation model

- standard ASCII format (latitude, longitude, latitude rate, longitude rate, vertical rate)
- 1°, 0.25° or 0.1° grid size
- bilinear interpolation
- similar format to geoid model
- planar assumption < 0.01 mm/yr error for 1° grid size
- accommodates some localised deformation and strain (depending upon grid size)

Limitations of rigid plate and 14 parameter models

- localised deformation distributed over model
- does not work where differential geodetic rates occur
- assumes rigid or uniformly deforming tectonic plate

Incorporating Episodic
Events (e.g. earthquakes)
into a Deformation Model

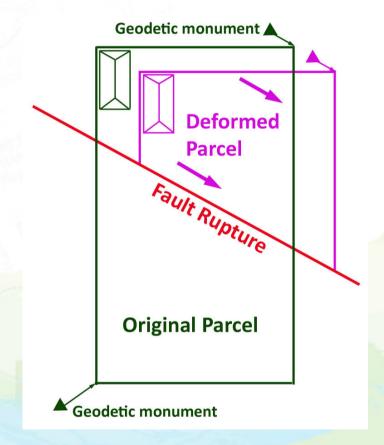

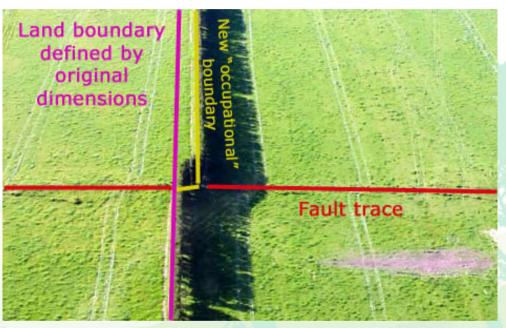

Why episodic events need to be modelled in

Localised deformation should result in coordinate changes to reflect visible reality

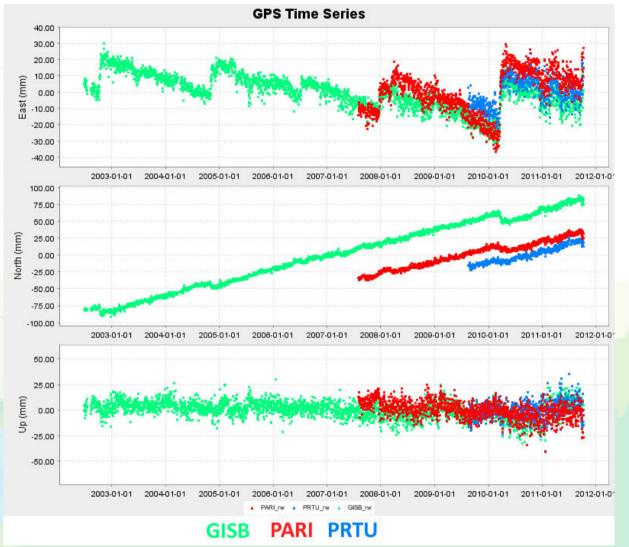

Typical time-series in a deforming zone

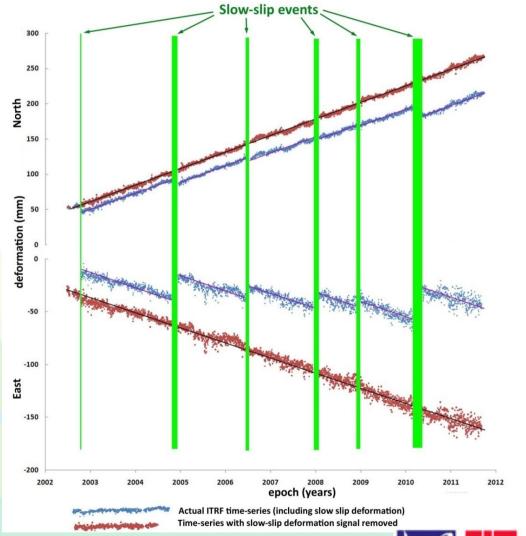

Time-series modelling

Separating seismic and secular (interseismic) deformation from time-series

Seismic patch is a sum of all non-secular (episodic) deformation between reference and measurement epoch

Nested model for deformation patch

Model Inputs –

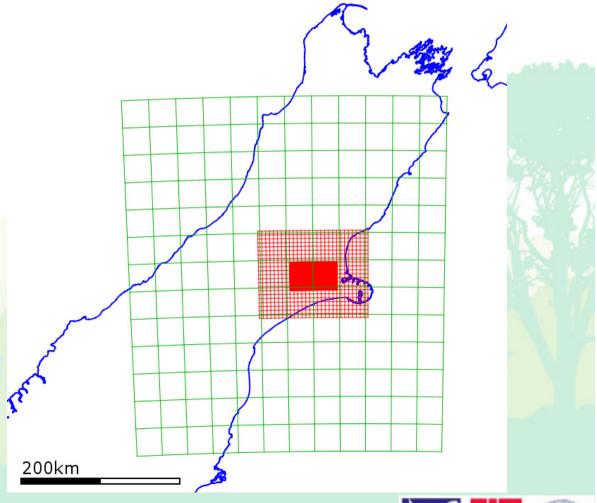

InSAR

LiDar & High-res imagery

analysis of seismic data

Repeat GNSS
obs of dense passive
network
(Strong argument for
maintaining passive
geodetic infrastructure)

Terrestrial surveys

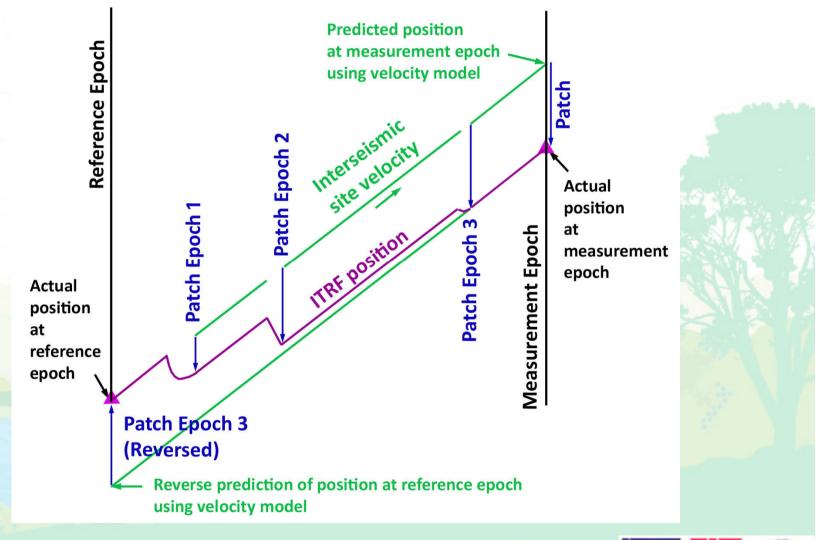

Two modes of deformation - concept

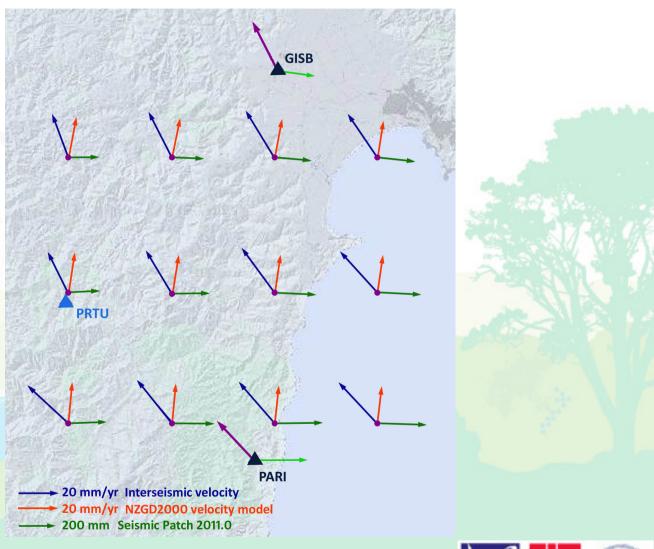

Two modes of deformation in practice

secular model (blue)

patch model (green)

existing model (orange)

Example

Rover (PRTU) ITRF2008 Epoch 2011.008 52.3646"

ITRF2008 Epoch 2011.008 S 38° 48' 51.0946" E 177° 41'

The ITRF site velocity from interseismic velocity model:

E -0.0108 m/yr

N 0.0217 m/yr

The seismic patch model at epoch 2011.0 $\Delta E = 0.183 \text{ m}$ $\Delta N = 0.008 \text{ m}$

NZGD2000 (estimated from model) S 38° 48' 51.1026" E 177° 41'

52.3620"

NZGD2000 (tabulated) S 38° 48' 51.1021" E 177° 41'

52.3619"

Tabulated – estimated: △E -0.002 m △N 0.014 m

Rigid plate case study (Australia)

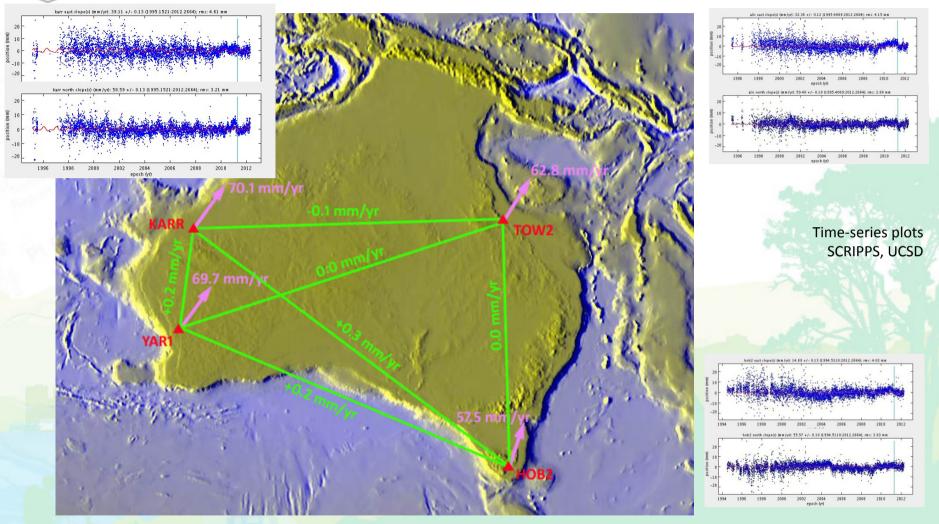

Australian Plate Deformation

purple arrows – tectonic movement, green lines – baseline changes per year

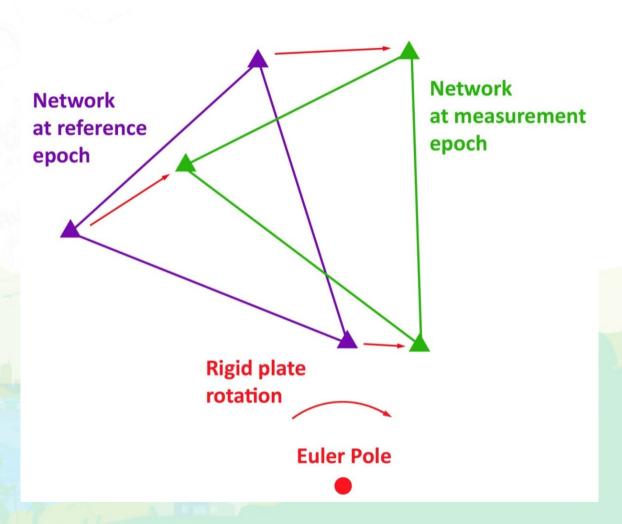

Effect of Rigid plate rotation on GNSS baselines

Australian
Plate rotates at ~0.63° / Ma

=

5 mm rotation of a 30 km GNSS baseline after only 15 years

e.g. holding rigid plate coordinates at an early epoch fixed for static processing or RTK at later epochs

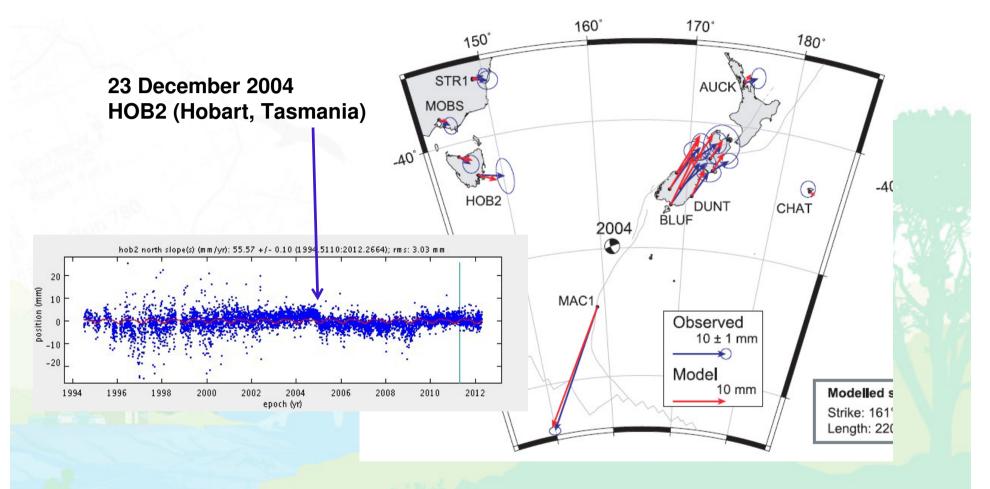

Far-field deformation effects on rigid plate

Far-field deformation from great earthquakes around the Australian margin (e.g. Mw8.1 23 December 2004 Macquarie Island, from Watson et. al, 2010)

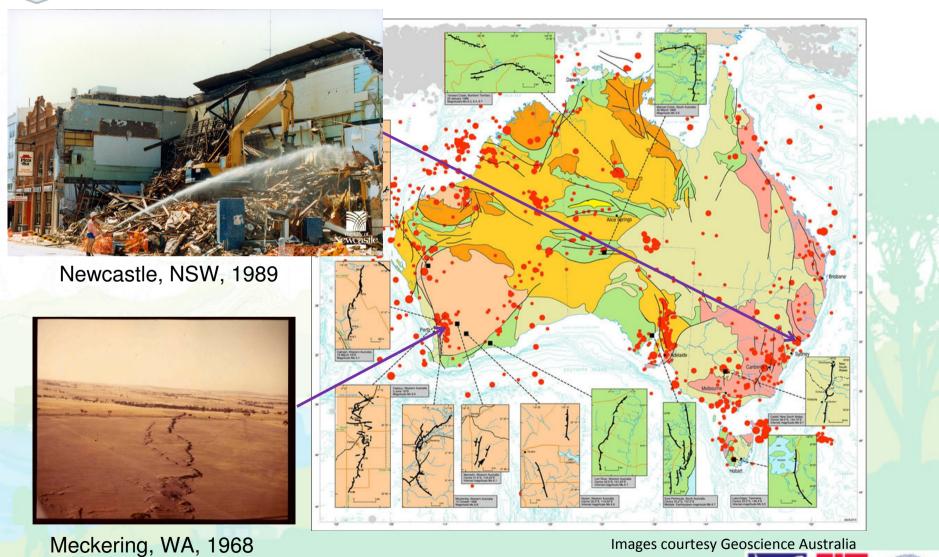

Intraplate deformation

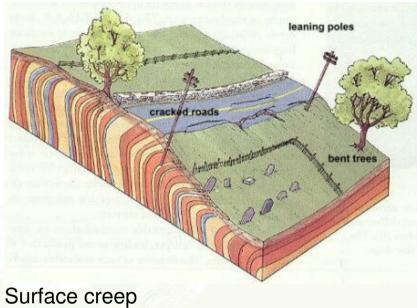

Localised deformation

Sedimentary basins and non-bedrock sites can be subject to significant localised deformation

Subsidence

Australian Example - using AUSPOS

1 User Data

All antenna heights refer to the vertical distance from the Ground Mark to the Antenna Reference Point (ARP).

Station (s)	Submitted File	Antenna Type	Antenna	Start Time	End Time
			Height (m)		
0015	0015241w.080	SOK_GSR2700IS NONE	0.910	2008/08/28 22:05:00	2008/08/29 08:30:30

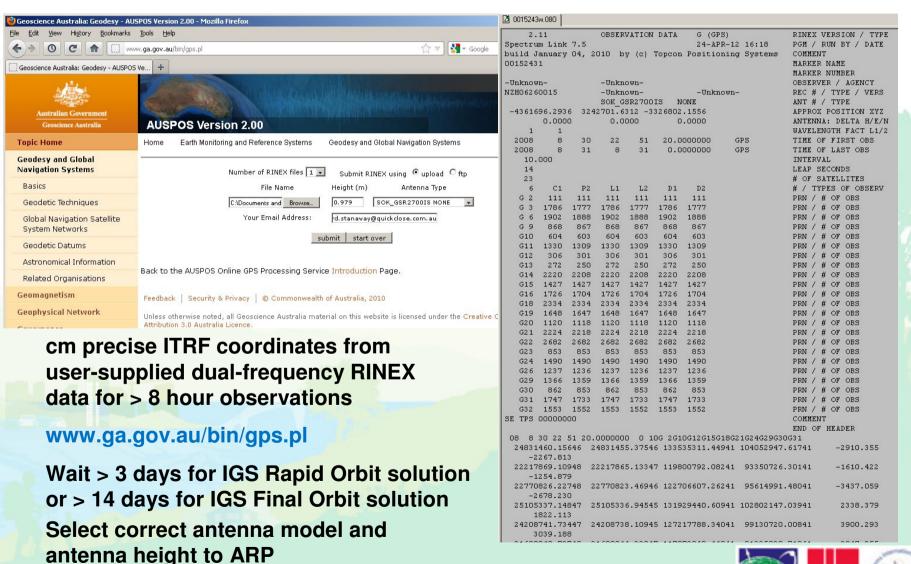

Using AUSPOS

AUSPOS GPS Processing Report

April 24, 2012

This document is a report of the GPS data processing undertaken by the AUSPOS Online GPS Processing Service (version: AUSPOS 2.0) . The AUSPOS Online GPS Processing Service uses International GNSS Service (IGS) products (final, rapid, ultra-rapid depending on availability) to compute precise coordinates in ITRF anywhere on Earth and GDA94 within Australia. The Service is designed to process only dual frequency GPS phase data.

Date	User Stations	Reference Stations	Orbit Type
2008/08/28 22:05:00	0015	ADE1 BEE2 BUR2 CEDU MOBS	IGS final
		PARK STR1 SYDN TID1	

4.1 Cartesian, ITRF2008

Station	X (m)	Y (m)	Z (m)	ITRF2008 @
0015	-4361680.131	3242720.715	-3326809.666	28/08/2008

5.1 Coordinate Precision - Geodetic, One Sigma

Station	σ East (m)	σ North (m)	σ Up (m)
0015	0.001	0.001	0.003

! Kinematic coordinates at epoch of observation

Example

3.1 Cartesian, GDA94

Station	X (m)	Y (m)	Z (m)
0015	-4361679.624	3242720.803	-3326810.422

3.2 Geodetic, GRS80 Ellipsoid, GDA94

Station	Latitude	Longitude	Ellipsoidal	Derived AHD
	(DMS)	(DMS)	${\tt Height(m)}$	(m)
0015	-31 38 33.60805	143 22 14.83619	87.237	73.468

3.3 MGA Grid, GRS80 Ellipsoid, GDA94

Station	East	North	Zone	Ellipsoidal	Derived AHD
	(m)	(m)		Height (m)	(m)
0015	724826.751	6496729.544	54	87.237	73.468

$$T_x = -0.06386(m)$$

$$T_y = 0.00023(m)$$

$$T_z = 0.04521(m)$$

$$S_c = 1.1308e - 08$$

$$R_x = 1.07834e - 07(radians)$$

$$R_y = 9.49620e - 08(radians)$$

$$R_z = 9.37467e - 08(radians)$$

The above transformation parameters are only valid for the epoch 28/08/2008.

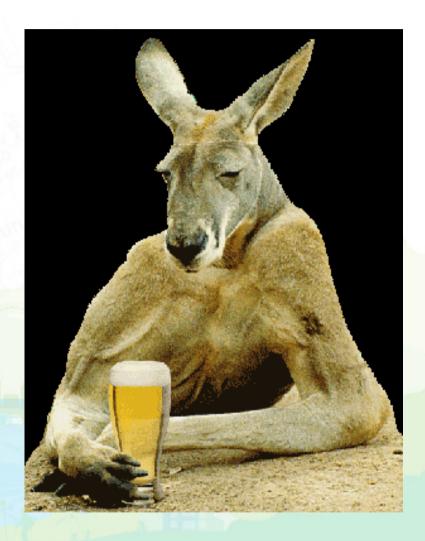

After a long day hopping across dry parameter space, a cold beer is near.

Thank you!

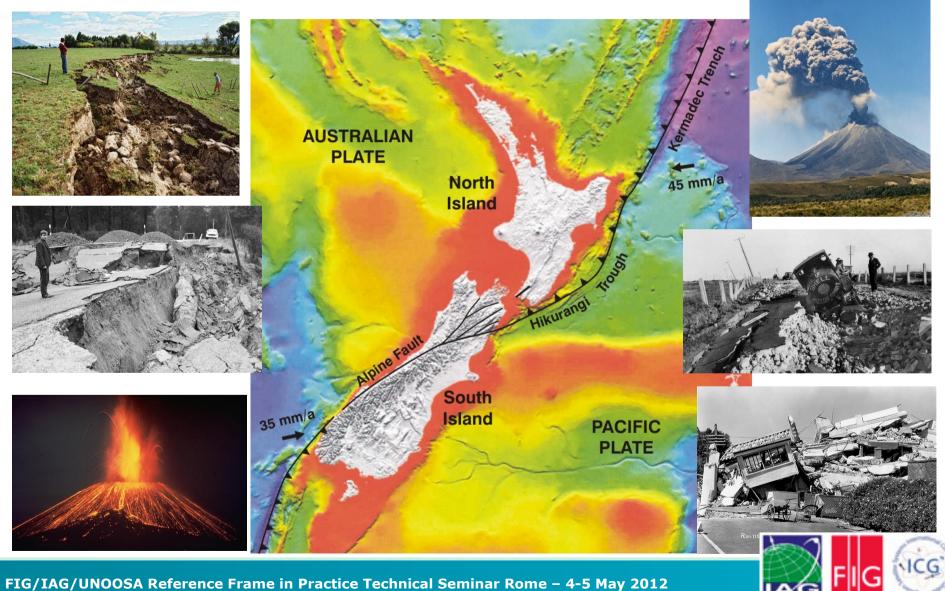

But we don't live on a stable planet

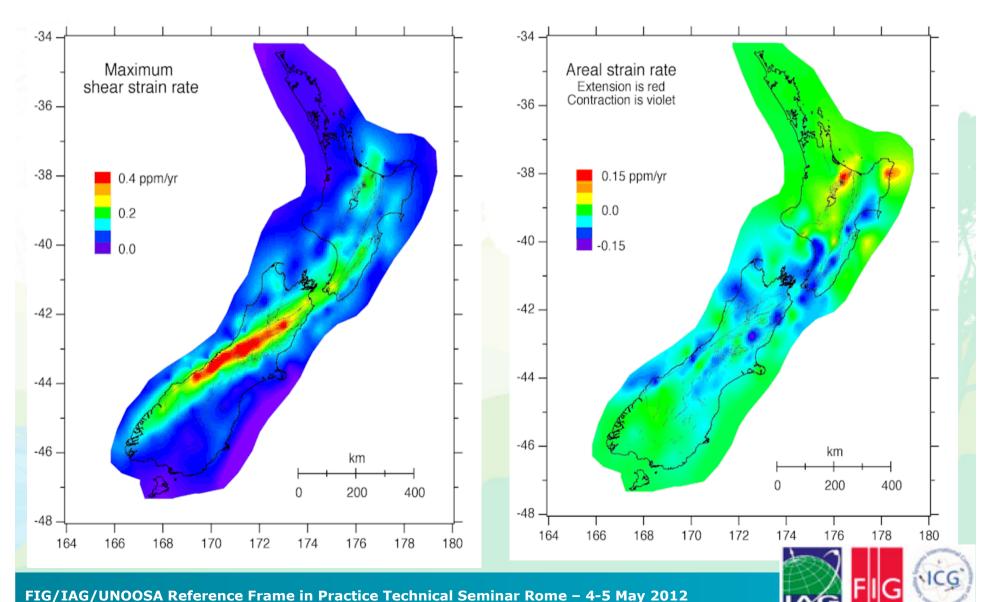

Measuring deformation - strain

Limitations with NZGD49

Regional distortions up to 5m present
Built up in a piecemeal fashion
Incompatible with global systems
It is of limited spatial coverage
It is static

NZGD2000

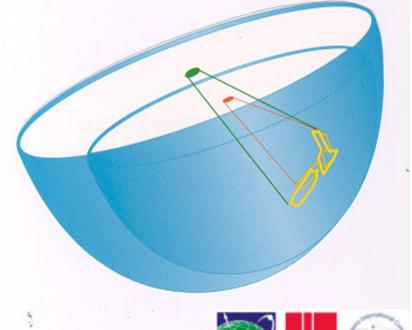

1998 – NZ introduced NZGD2000 (ref epoch 1 Jan 2000)

- geocentric origin
- aligned with the ITRS
- ITRF96 with epoch 2000.0 coordinates

NZGD2000 - semi-dynamic datum

generalised motion of points
 modelled using a deformation
 model

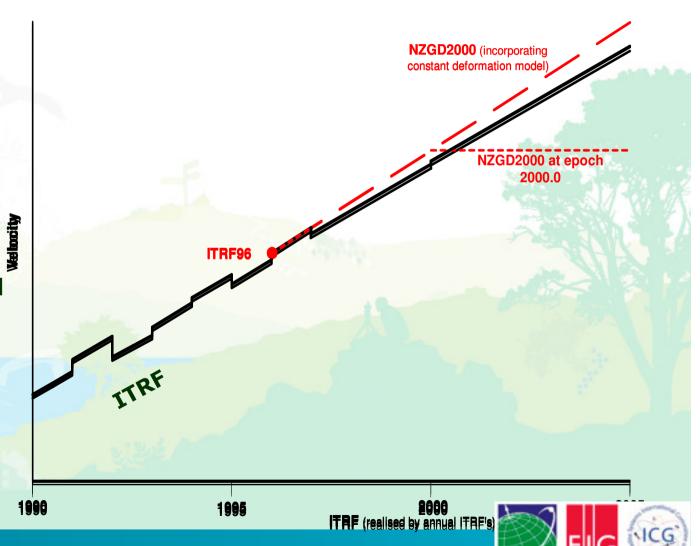

NZGD2000

- Tied to ITRF96
- Generalised motion of points modelled using a constant velocity deformation model
- Epoch 2000 coordinates generated at 2000.0

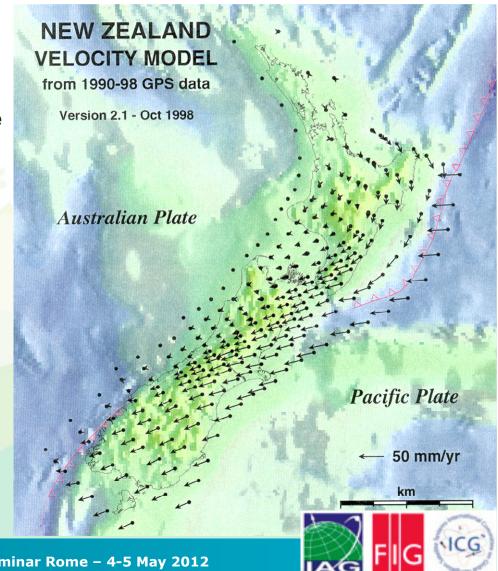

NZGD2000

Semi-dynamic datum

- deformation model calculated by holding fixed the Aust plate and uses the euler rotation parameters to bring in terms of ITRF96
- velocities provided in a rectangular grid
 (0.1 degree) for ease of computations
- current deformation model has horizontal constant velocities only
- generated using repeat surveys
 between 1992 and 1998
- enables propagation of coordinates and observations between reference epoch and observation epoch

Where are we at

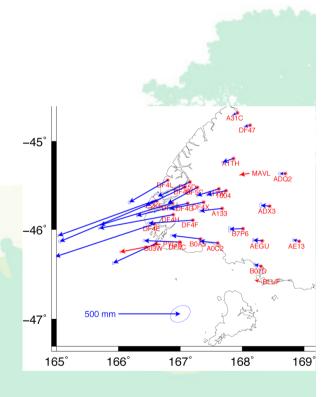

What has gone well

- User acceptance
- Implementation of the deformation model in LINZ
- Maintaining the accuracy of datum

Issues

- Managing the deformation model
- Accuracy of deformation model versus CORS real time positions
- Managing the spatial alignment of the cadastral system
- Misalignment of readjusted historic geodetic control with new surveyed geodetic control

Future developments

- Updating the Deformation Model
- Vertical Deformation Model
- CORS Real Time Tools for Managing Coordinates
- Tie to the ITRF Going Fully Dynamic?

Darfield Earthquake

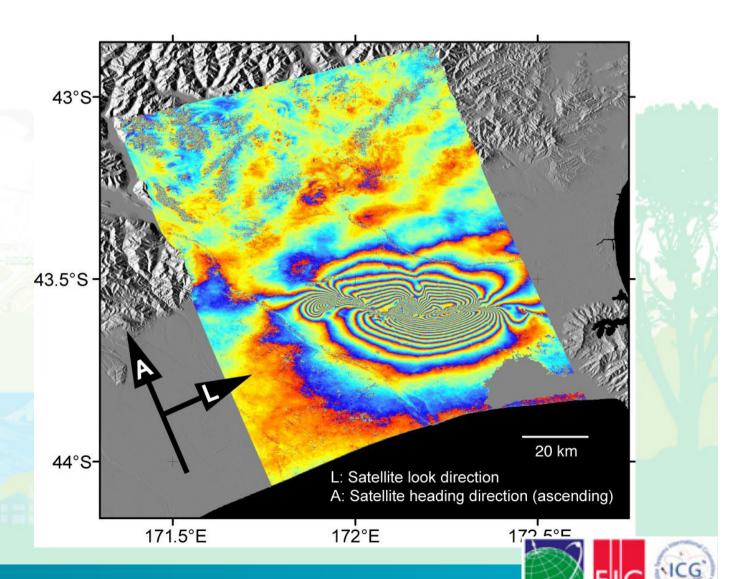

InSAR interference pattern as a result of the Darfield earthquake

Each coloured fringe represents 1.5 cm of ground displacement in line-of-sight to the satellite

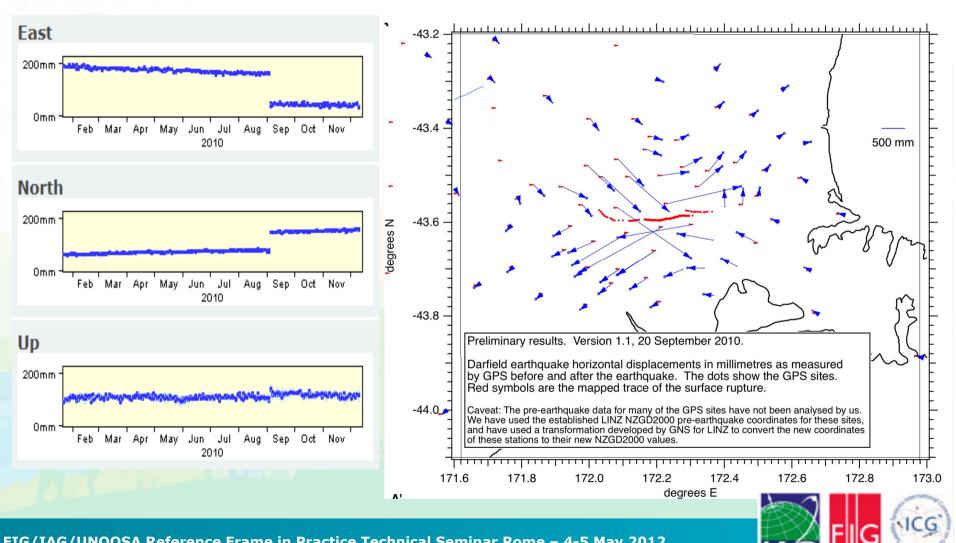

Incoherent regions indicate ground damage

Creating a patch -**Canterbury earthquakes**

Impact on geodetic control

Range is based on the distance from the centre of the fault rupture.

Maximum Range	Geodetic marks	Cadastral control	Total marks
(km)	(order 5 or better)	(order 6 or better)	
0-20	223	4816	56835
20-40	1269	49538	565892
40-60	3176	28632	387606
60-80	673	3681	143593
80-100	487	2182	103995
Total	5828	88849	1257921

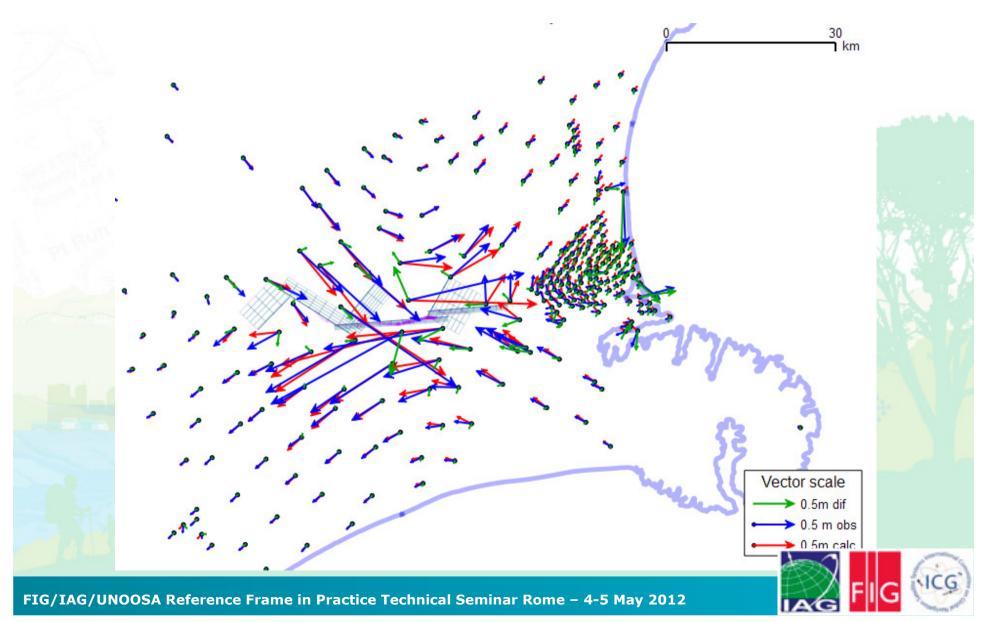

Model out the effects of the earthquake

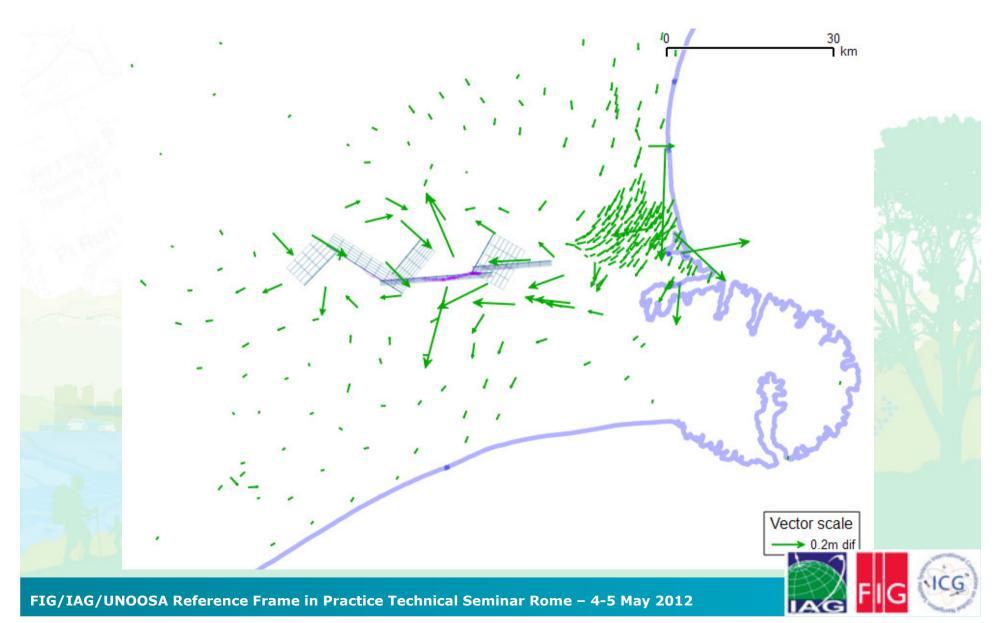

Residuals

Summary

- The incorporation of a deformation model in NZGD2000 has enabled
 - the life of the datum to be lengthened
 - new observations to be integrated with old observations
 - the accuracy of the datum to be maintained
- But
 - how complex deformation events will be incorporated in the model have yet to be fully determined and resolved

Four dimensional deformation models for Terrestrial Reference Frames
